

Live/dead algal analysis with the Attune NxT Flow Cytometer

Introduction

For several years, microalgae have been an important source of nutritional products, fuel alternatives, and chemicals. The research into these types of algae for foods, pharmaceuticals, and other chemicals is quickly growing due to the importance of finding more sustainable and less expensive means to produce these products. Depending upon the species, microalgae can be grown in open raceways, photobioreactors, or fermenters. Regardless of the production systems, the maintenance of a healthy culture and the ability to monitor that culture is essential. Flow cytometry is an ideal tool for investigating and monitoring algal cultures. In general, strain improvement in microalgae requires the ability to screen several strains for potential improvement in the target product. The Invitrogen™ Attune™ NxT Flow Cytometer offers superior speed and the ability to handle the large and adherent forms of algal culture. In addition, the acoustic focusing technology and Attune™ NxT Auto Sampler allow for high-throughput screening of strains for improved phenotyping and minimal clogging.

Methods

1. 400 µL of *N. oculata* culture was microwaved for 20 seconds.
2. The microwaved culture was allowed to cool to ambient temperature.
3. 10 µL of 5 mM SYTOX Green stain was mixed with 990 µL of Nanopure water:
Final concentration = 50 µM SYTOX Green stain
4. 5 µL of 50 µM SYTOX Green stain was added to 95 µL of algal culture:
N. oculata live (viable culture sample) and
N. oculata dead (microwaved sample)
5. Treated cultures were incubated in the dark for 30 minutes at ambient temperature.
6. Cultures were diluted 20-fold in PBS, pH 7.4, prior to analysis by flow cytometry.

Algal viability

Species: *Nannochloropsis oculata*

Materials

- Invitrogen™ SYTOX™ Green Dead Cell Stain (S34860)
- Nanopure™ water
- *N. oculata* culture in artificial seawater medium (approximately 1 mL)
- Phosphate-buffered saline (PBS), pH 7.4

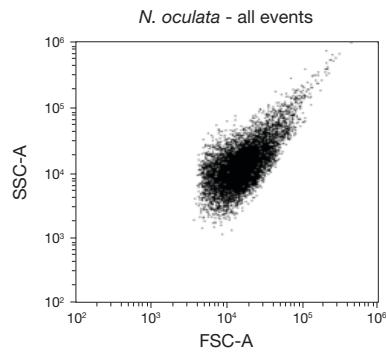

Figure 1. Forward scatter (FSC) vs. side scatter (SSC) dot plot of algae (*N. oculata*). FSC threshold was set to 5.0 to remove debris from the analysis, FSC voltage was set at 440, and SSC voltage was set at 350.

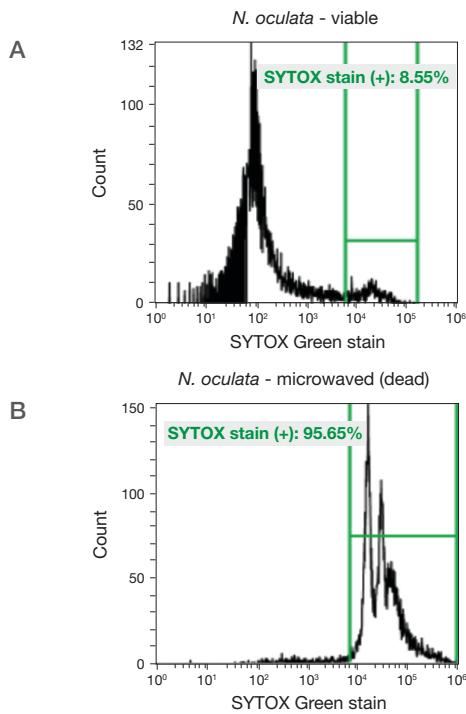

Figure 2. Determining viability of *N. oculata*. SYTOX Green stain was added to normal or microwaved cultures of *N. oculata*, and viability was determined with the Attune NxT Flow Cytometer. **(A)** Normal culture of *N. oculata* showing less than 10% SYTOX Green-positive cells (dead cells). **(B)** *N. oculata* culture microwaved for 20 seconds, demonstrating that these conditions caused a large increase in dead cells (>95% SYTOX Green-positive cells).

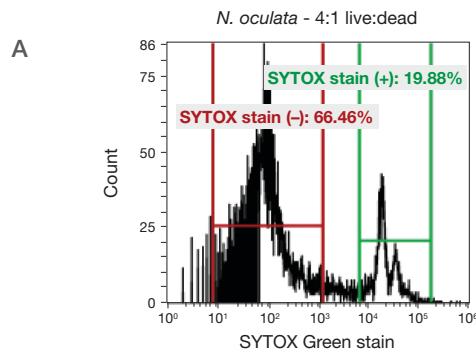

Figure 3. Analysis of mixtures of live and dead cultures of *N. oculata*. Live and dead (microwaved) cultures of *N. oculata* were mixed together in different proportions and analyzed with the Attune NxT Flow Cytometer. Viability of cells was determined using the SYTOX Green stain. **(A)** 4:1 mix of live:dead algal cells. **(B)** 1:1 mix of live:dead algal cells. **(C)** 1:4 mix of live:dead algal cells.

Conclusion

Live and dead algae were analyzed with the Attune NxT Flow Cytometer and SYTOX Green Dead Cell Stain. The ability to quantitate different amounts of live and dead algal cells offers a screening tool for laboratories utilizing these types of organisms.
